Neurofibromatosis

Neurofibromatosis (NF) is a genetic disorder causing skin abnormalities and tumors that form on nerve tissues. These tumors can be small or large and can occur anywhere in the body, including the brain, spinal cord, large nerves, or smaller nerves. NF affects persons of both sexes and all racial groups. There are 2 types of neurofibromatosis, called NF1 and NF2. These are 2 distinct disorders that are caused by mutations (changes) in different genes. NF1 is also referred to as Von Recklinghausen disease and is a rather common genetic disease, affecting approximately 1 in 4000 individuals. Some patients who have NF1 only display characteristic skin abnormalities such as café-au-lait spots, which are flat, hyperpigmented (darker than surrounding skin) areas. Other patients can have severe physical complications such as malignant (cancerous) tumors or have mental retardation. The July 16, 2008, issue of JAMA includes an article about the learning deficits associated with NF. Learning disability is the most frequent complication in children with NF1.

NF2 is much more rare than NF1, affecting less than 1 in 30,000 individuals, usually becoming apparent in the late teens, and typically causing hearing loss and problems with balance due to tumors on nerves to the ears.

**Diagnosis and Genetics**

About 50% of NF patients have an affected parent, but in 50% the mutation occurs spontaneously in a family with no previous history of NF. The diagnosis of NF1 and NF2 is based on clinical symptoms. The NF1 diagnosis can usually be made before the age of 6, whereas the symptoms of NF2 often only arise in the late teens. Since the 2 genes that cause NF1 and NF2 have been discovered, genetic testing is also available.

**Treatment**

Because of the wide range of symptoms and complications that can arise in NF1 and NF2, patients should be monitored by a team of specialists. There is currently no cure for NF1 or NF2. Surgical treatment is aimed at alleviating the symptoms that arise when NF tumors compress nearby bodily tissues and can cause damage to those tissues or organs. Chemotherapy (anticancer drugs) may also be offered when the tumors associated with NF are malignant. This occurs in less than 10% of persons who have NF.
