Association of Distance From a Transplant Center With Access to Waitlist Placement, Receipt of Liver Transplantation, and Survival Among US Veterans

David S. Goldberg, MD, MSCE; Benjamin French, PhD; Kimberly A. Forde, MD, MHS; Peter W. Groeneveld, MD, MS; Therese Bittermann; Lisa Backus, MD, PhD; Scott D. Halpern, MD, PhD; David E. Kaplan, MD, MSc

IMPORTANCE Centralization of specialized health care services such as organ transplantation and bariatric surgery is advocated to improve quality, increase efficiency, and reduce cost. The effect of increased travel on access and outcomes from these services is not fully understood.

OBJECTIVE To evaluate the association between distance from a Veterans Affairs (VA) transplant center (VATC) and access to being waitlisted for liver transplantation, actually having a liver transplant, and mortality.

DESIGN, SETTING, AND PARTICIPANTS Retrospective study of veterans meeting liver transplantation eligibility criteria from January 1, 2003, until December 31, 2010, using data from the Veterans Health Administration’s integrated, national, electronic medical record linked to Organ Procurement and Transplantation Network data.

MAIN OUTCOMES AND MEASURES The primary outcome was being waitlisted for transplantation at a VATC. Secondary outcomes included being waitlisted at any transplant center, undergoing a transplantation, and survival.

RESULTS From 2003-2010, 50,637 veterans were classified as potentially eligible for transplant; 2895 (6%) were waitlisted and 1418 of those were waitlisted (49%) at 1 of the 5 VATCs. Of 3417 veterans receiving care at a VA hospital located within 100 miles from a VATC, 244 (7.1%) were waitlisted at a VATC and 372 (10.9%) at any transplant center (VATC and non-VATCs). Of 47,219 veterans receiving care at a VA hospital located more than 100 miles from a VATC, 1174 (2.5%) were waitlisted at a VATC and 2523 (5.3%) at any transplant center (VATC and non-VATCs). In multivariable models, increasing distance to closest VATC was associated with significantly lower odds of being waitlisted at a VATC (odds ratio [OR], 0.91 [95% CI, 0.89-0.93] for each doubling in distance) or any transplant center (OR, 0.94 [95% CI, 0.92-0.96] for each doubling in distance). For example, a veteran living 25 miles from a VATC would have a 7.4% (95% CI, 6.6%-8.1%) adjusted probability of being waitlisted, whereas a veteran 100 miles from a VATC would have a 6.2% (95% CI, 5.7%-6.6%) adjusted probability. In adjusted models, increasing distance from a VATC was associated with significantly lower transplantation rates (subhazard ratio, 0.97; 95% CI, 0.95-0.99 for each doubling in distance). There was significantly increased mortality among waitlisted veterans from the time of first hepatic decompensation event in multivariable survival models (hazard ratio, 1.03; 95% CI, 1.01-1.04 for each doubling in distance). For example, a waitlisted veteran living 25 miles from a VATC would have a 62.9% (95% CI, 59.1%-66.1%) 5-year adjusted probability of survival from first hepatic decompensation event compared with a 59.8% (95% CI, 56.3%-63.1%) 5-year adjusted probability of survival for a veteran living 100 miles from a VATC.

CONCLUSIONS AND RELEVANCE Among VA patients meeting eligibility criteria for liver transplantation, greater distance from a VATC or any transplant center was associated with lower likelihood of being waitlisted, receiving a liver transplant, and greater likelihood of death. The relationship between these findings and centralizing specialized care deserves further investigation.

Centralization of specialized health care services is used to control costs, concentrate expertise, and minimize regional differences in quality of care. Such efforts are common in national health systems. In the United States, insurers regionalize care by contracting with centers of excellence for services like bariatric surgery, cardiac interventions, and treatment for some cancers. Although efficient, centralization may offset any gains in care delivery by increasing the distance between patients and hospitals. Prior studies relating geography to health care access found less access for rural patients and for those patients living far away from hospitals delivering specialized services. Few studies have examined specialized care restricted to a limited number of centers. Previous studies of access to care were limited by not knowing the total population in need of care.

Organ transplantation is a highly specialized service requiring concentrated medical and surgical expertise, resulting in de facto centralization in metropolitan regions. Veterans with Veterans Health Administration (VHA) benefits receive care at 1 of 128 Veterans Affairs (VA) hospitals or associated community-based clinics. Within the VA, liver transplantation is offered at only 5 VA transplant centers (VATCs) located in Houston, Texas (since 2008); Nashville, Tennessee; Pittsburgh, Pennsylvania; Portland, Oregon; and Richmond, Virginia. Veterans with secondary insurance (ie, Medicare) may obtain care at either a VATC or non-VATC. Patients at the VA lacking other health insurance generally receive care at a VATC except in rare emergencies (ie, fulminant hepatic failure).

Liver transplantation in the VA system serves as a model to study the association between distance and access to centralized medical resources. We tested the hypothesis that increasing distance between a patient and a liver transplant center (ie, VATC) is associated with a lower likelihood of being waitlisted for transplantation, a lower likelihood of getting a liver transplant, and an increased risk for mortality.

Methods

We evaluated liver transplantation in the VA between January 1, 2003, and September 20, 2012. January 1, 2003, was selected as the start date because it was about 1 year after the implementation of the current model for end-stage liver disease (MELD) allocation system. MELD shifted liver transplantation priority away from wait time to illness severity.

The study was approved by the institutional review boards at the Philadelphia VA Medical Center and the University of Pennsylvania, which included a waiver of informed consent.

Veterans Eligible for Waitlisting at a VATC

Any veteran with VHA health benefits who used the VA health system was eligible for inclusion. We queried the VHA’s Corporate Data Warehouse to identify transplant-eligible veterans meeting the following minimal waitlisting criteria established by the American Association for the Study of Liver Diseases: cirrhosis with a complication of liver disease (ascites, variceal bleeding, or hepatic encephalopathy) or hepatocellular carcinoma. Transplant-eligible veterans were identified using a validated International Classification of Diseases, Ninth Revision, coding algorithm. We excluded veterans aged 70 years or older (only 4 veterans aged 70 years were waitlisted at a VATC from 2003-2010) with malignancies precluding transplantation or having the human immunodeficiency virus (Table 1 in Supplement).

We only included veterans with incident decompensated cirrhosis from January 1, 2003, until December 31, 2010, to ensure sufficient follow-up for outcomes assessment. Veterans Affairs physicians may not directly refer veterans who have secondary insurance to non-VA transplant facilities. They may, however, inform patients of their ability to refer themselves for non-VA health care. The VA does not reimburse veterans for co-pays or deductibles related to non-VA care.

We restricted our cohort to veterans who were active users of VA outpatient care to ensure the ability to be referred for liver transplantation in the VA system. We defined active users as patients who were seen in VA outpatient clinics for at least 2 physician or clinician outpatient visits in the 365 days following the first decompensation event or hepatocellular carcinoma event (including the index visit if outpatient). Two visits were required based on previous studies evaluating use of VA care, and the assumption that to complete testing prior to referral to a VATC, a veteran must have at least 2 outpatient visits. Veterans were assigned to a local VA medical hospital using Corporate Data Warehouse data, which identified the VA medical hospital where a patient received his or her medical care. Patients receiving care at more than 1 VA facility were assigned to the first hospital where he or she met the coding algorithm criteria for having decompensated cirrhosis, hepatocellular carcinoma, or both.

Identification of Waitlisted Veterans

We cross-referenced Social Security numbers of all waitlisted liver transplant candidates from 2003-2012 using the Organ Procurement and Transplantation Network (OPTN) database linked with the VA Corporate Data Warehouse. Among the 110 US liver transplant centers, the waitlists of only 5 (the VATCs) were solely composed of patients with VA insurance, and these transplant centers could be discriminated based on the distribution of zip codes of the waitlisted patients at each center.

Statistical Analysis

Access to Waitlisting

In our primary analysis, we evaluated the relationship between a transplant-eligible veteran’s distance from the local VA hospital to a VATC and being placed on the waitlist for a liver transplant at a VATC. Secondarily, we evaluated the association between distance to a VATC and being placed on the waitlist at any transplant center (VATC and non-VATC) to determine whether access to a local non-VATC mitigates this relationship between distance and waitlisting. We chose a binary waitlisting outcome because access to transplantation once waitlisted is based on severity of illness not waiting time unlike kidney transplantation.

Distance was modeled as a continuous variable. The relationship between distance and waitlisting was not linear so distance was linearized by log transformation in the log 2 base scale. In a secondary analysis, distance was modeled as a categorical variable with 5 categories. To our knowledge, no prior
AccesstoLiverTransplantationintheVA

WeassumedthatveteransreceivingcareatVAwithindistanceof100milesfromVATCwouldliveathomeafterdischargefromthetransplanthospitalizationgiventhattraveltimesfortheseveteranswouldbelessthan90minutes.Thus,thefirstdistancecutpointwasselectedtobe100miles.Distanceslongererthan100mileswerecategorizedrelativetotraveltimesormodeoftransportationtoVATC(ie,necessitytotravelbyplaneforthoseliving>500milesoffromVATC).Privacyregulationsprecludedouraccessatoatient’shomeaddress.Consequently,thest Shortest distance in miles was measured between the VA medical hospital where the patient received routine care and the closest VATC or non-VA transplant facility.

Weassumedthedistributionofthese covariatesmimickedthebroaderchronicliverpopulation at each VA medical hospital.

Transplantation

The distance to a transplant center may affect the likelihood of receiving a liver transplant. For example, patients living closer to a transplant center might have increased access to transplantation because they can reach the center in the narrow time window of an organ offer, or by virtue of proximity, serve more readily as a backup recipient. To evaluate this, we analyzed all waitlisted veterans, and modeled deaths while waitlisted as identified by OPTN coding or within 90 days of being removed from the list. Deaths were identified from the Social Security Death Master File found within OPTN. Pretransplant deaths were modeled as competing risks because death while on the waitlist serves as a competing risk to transplantation.

We fit competing risk Cox regression models with transplant as the outcome and all other waitlist removals (eg, condition improved) other than death (modeled as the competing risk) as censoring events. The exposure was distance from a patient’s home VA hospital to a VATC. Covariates included sex, race/ethnicity, age, laboratory MELD score, and albumin measured when waitlisted, diagnosis, and hepatocellular carcinoma (binary yes or no as to whether a patient was receiving additional waitlist priority for hepatocellular carcinoma). We tested for interactions between distance and being waitlisted at a VATC to determine if the probability of being waitlisted is directly influenced by distance. We used a robust standard error estimator to adjust for the clustering of veterans within VA hospitals.

Survival

The relationship between mortality and distance to a VATC among all waitlisted veterans was modeled with Cox regression. Time from the first hepatic decompensation event to death or a censoring event (eg, condition improved) was modeled with the exposure variable being distance from the patient’s home hospital to a VATC. Follow-up began at the date of first hepatic decompensation event to account for the time a patient first became eligible for transplant, which may have been associated with delays in being waitlisted as a function of distance. We adjusted the model for covariates available in OPTN (sex, race/ethnicity, age, laboratory MELD score, albumin level measured when waitlisted, diagnosis, and hepatocellular carcinoma) and insurance status at the time of waitlisting. Residential-level poverty was adjusted for using OPTN zip code data. Death dates were ascertained as specified above. We used a robust variance estimator to adjust for clustering within VA hospitals. The proportional hazard assumption was tested for using Schoenfeld residuals.

Sensitivity Analyses

Although veterans with decompen sated cirrhosis met minimal clinical criteria for being waitlisted, a MELD score of 15 or greater may better determine eligibility. In a preplanned sensitivity analysis, we restricted our cohort to veterans having MELD scores of 15 or higher following the diagnosis of decompensated cirrhosis, hepatocellular carcinoma, or both. The influence of a patient’s base hospital having advanced liver care available (defined by being located within 20 miles of any transplant center, being affiliated with an academic liver transplant center, and having a clinician specialized in hepatology) was modeled by a distance × advanced liver care interaction analysis. Availability of secondary insurance status (defined as none, Medicaid, secondary non-Medicaid, or Medicaid plus secondary non-Medicaid) was modeled as a covariate for the 45 792 (90.4%) of the cohort who had this information available in the VA Corporate Data Warehouse (10% had missing data or insurance status reported as unknown).
Statistical significance was defined as \( P < .05 \) using 2-sided tests. The final multivariable models also include variables with biological plausibility for the association with the outcome, even if the \( P \) value was above the prespecified \( P \) value threshold (ie, diagnosis). All analyses used Stata version 13.0 (StataCorp), including the xtggee module.

### Results

Among all veterans in the United States having VHA health benefits and using VHA medical care, 79 899 had incident decompen-sated cirrhosis or hepatocellular carcinoma (of any stage) and used VA outpatient services from 2003-2010. Although hepatocellular carcinoma stage could not be ascertained, which affects transplant eligibility,\(^6\) results were unchanged when patients with hepatocellular carcinoma were excluded. Of the 79 899 veterans, 29 262 were excluded (18 041 were aged ≥70 years and 11 221 were <70 years, but had a malignancy precluding transplantation). This left a total analytic cohort of 50 637.

Overall, 2895 (5.7%) veterans meeting our predefined criteria of using VA outpatient care were waitlisted (1418 [49.0%] at a VATC and 1477 [51.0%] at a non-VATC). Waitlisted veterans had significantly more VA clinician visits than veterans who were not waitlisted, but there were no differences based on distance to a VATC. Demographic characteristics are listed in Table 1 (additional clinical data in eTable 2 in Supplement).

### Validation of Distance

Our method of measuring distance was validated by analyzing the cohort of veterans waitlisted at the Pittsburgh VATC (eTable 3 in Supplement). Because the home zip codes of waitlisted veterans is provided in OPTN data, the distance from the centroid of a respective veteran’s home zip code to the Pittsburgh VATC was compared with the measured distance from that veteran’s local VA hospital to the Pittsburgh VATC. The median distance between these 2 measured distances was 18.7 miles (interquartile range, 5.3-55.7 miles), with nearly 90% of such veterans who were categorized as being within 100 miles based on distance from a local VA hospital remaining in that category when using home zip code as the measure (eTable 3 in Supplement).

### Multivariable Regression Results

In multivariable models, increasing distance to a VATC was associated with significantly lower odds of being waitlisted either at a VATC or any transplant center (Table 2). The odds ratio (OR) in the multivariable generalized estimating equation model evaluating distance and waitlisting at a VATC was 0.91 (95% CI, 0.89-0.93; \( P < .001 \); Table 2). For example, a veteran living 25 miles from a VATC would have a 7.4% (95% CI, 6.6%-8.1%) adjusted probability of being waitlisted, whereas a veteran 100 miles from a VATC would have a 6.2% (95% CI, 5.7%-6.6%) adjusted probability. The OR signifies a 9% lower odds of being waitlisted at a VATC between 2 populations whose distance from a local VA hospital to a VATC differs by a multiplicative factor.

<sup>a</sup> Center-specific covariates of proportion of veterans with mental illness and percentage of veterans with a low socioeconomic status excluded from final model for listing at VATC because they were not significant in univariable or multivariable models (P > .50) and were not confounders of the relationship between distance and waitlisting. None of the variables were collinear and the models were not overfit due to a large number of outcomes relative to the number of covariates examined.

<sup>b</sup> The odds ratio (OR) for distance corresponds to the difference in the odds of being waitlisted between 2 populations whose distance from a local VA center to a VATC differs by a multiplicative factor of 2.

<sup>c</sup> The number within each racial/ethnic category represents the total number of transplant-eligible veterans receiving care at a VA center with that specific racial/ethnic composition. The waitlisting rate at a VATC is 2.6% (89/3461) for 76%-100% white, 3.0% (670/22 026) for 51%-75% white, 2.6% (539/21 107) for 26%-50% white, and 3.0% (120/4403) for 0%-25% white. The waitlisting rate at any transplant center was 4.7% (163/3461) for 76%-100% white, 5.9% (1296/22 026) for 51%-75% white, 5.8% (1213/21 107) for 26%-50% white, and 5.5% (233/4403) for 0%-25% white.

<sup>d</sup> Omnibus P value for the overall category.

<sup>e</sup> The median center age was based on center-level data from the VA Hepatitis C Clinical Case Registry, and for each VA center, there is an age in years that is the median center age. The OR thus signifies the increase in the odds of waitlisting for every increase in 1 year of the median center age when comparing 2 centers.

Abbreviations: IQR, interquartile range; VATC, VA transplant center.

<sup>a</sup> Data presented per VA medical center and distance category. The 5 distance categories reflect the distribution of the data and cut points in the relationship between distance and waitlisting. Only veterans receiving care at a VA center within 100 miles of a VATC would be expected to have the opportunity to live at home after discharge from the transplant hospitalization.

<sup>b</sup> Derived from χ<sup>2</sup> tests for the proportion of veterans waitlisted (yes or no) within each distance category or the Kruskall-Wallis test when comparing median and ranges between centers across distance categories.

<sup>c</sup> The median values for percentages listed at a VATC vs any transplant center do not add up because a different VA medical center may represent the median for different variables.

<sup>d</sup> From January 1, 2003, through December 31, 2007, the distance from a VA medical center to the closest VATC was measured from the Nashville VA for the 10 centers for which the Houston VATC is the closest because only 1 liver transplant was performed at the Houston VATC prior to January 1, 2008.

<sup>e</sup> For each VA center, this value represents the proportion of veterans eligible for inclusion in the study who were waitlisted at a VATC among eligible veterans waitlisted overall (ie, 20% if a specific center has 50 veterans waitlisted, of whom 10 are waitlisted at a VATC).
modeled as a categorical variable (eTables 4 and 5 in Supplement).

Categorical Analysis

The proportion of transplant-eligible veterans waitlisted for transplantation at any transplant center differed significantly by distance from a VATC (≤100 miles, 372/3417 [10.9%; 95% CI, 9.9%-12.0%]; 101-200 miles, 279/3122 [5.5%; 95% CI, 4.8%-6.1%]; 201-300 miles, 424/7906 [5.4%; 95% CI, 4.9%-5.9%]; 301-500 miles, 550/9528 [5.8%; 95% CI, 5.3%-6.3%]; >500 miles, 1270/24 664 [5.2%; 95% CI, 4.9%-5.4%]; P < .001; Table 3). Of 47 219 veterans receiving care at a VA hospital located more than 100 miles from a VATC, 1174 (2.5%) were waitlisted at a VATC and 2523 (5.3%) at any transplant center (VATC and non-VATCs). The proportion specifically waitlisted at a VATC was also significantly varied by distance to a VATC (≤100 miles, 244/3417 [7.1%; 95% CI, 6.3%-8.1%]; 101-200 miles, 142/3122 [2.8%; 95% CI, 2.3%-3.3%]; 201-300 miles, 184/7906 [2.3%; 95% CI, 2.0%-2.7%]; 301-500 miles, 245/9528 [2.6%; 95% CI, 2.3%-2.9%]; >500 miles, 603/24 664 [2.4%; 95% CI, 2.3%-2.6%]; P < .001; Table 3). Among all veterans who were waitlisted, the proportion specifically waitlisted at a VATC varied by distance. There was a broad range specifically waitlisted at a VATC across VA locations within each distance category (Table 3); however, when aggregated by distance, 66% of waitlisted veterans from the 8 VA hospitals within 100 miles of a VATC were waitlisted at a VATC compared with less than 51% across the other distance categories (Figure).

Access to Transplantation

Waitlisted veterans who received care more than 100 miles from a VATC were significantly less likely to receive a transplant once waitlisted at a VATC or at any transplant center (eTable 6 in Supplement). Among veterans waitlisted at a VATC, the proportion who received transplants at a VATC differed by distance from a VATC (≤100 miles, 156/244 [62.9%]; 101-200 miles, 76/142 [53.5%]; 201-300 miles, 103/184 [56.0%]; 301-500 miles, 125/245 [51.0%]; and >500 miles, 326/604 [54.1%]; P = .045). Among all waitlisted veterans, the proportion who received transplants at any transplant center varied significantly by distance from a VATC (≤100 miles, 262/372 [70.4%]; 101-200 miles, 164/279 [58.8%]; 201-300 miles, 243/424 [57.3%]; 301-500 miles, 294/550 [53.5%]; and >500 miles, 700/1270 [55.1%]; P < .001). In multivariable models of all waitlisted veterans, increasing distance from a local VA hospital to a VATC was associated with a 3% lower odds of transplantation at any transplant center between 2 populations of waitlisted veterans whose distance from a local VA hospital to a VATC differs by a multiplicative factor of 2 (subhazard ratio, 0.97 [95% CI, 0.95-0.98]; 0.95-0.98 for log2 based on distance variable; P = .001; Table 4).

Survival

The overall survival rate of waitlisted veterans from the time of hepatic decompensation event differed by distance from a local VA hospital to a VATC (Table 5). Although the 1-year survival rates were similar, they dispersed over time. In multivariable survival models of all waitlisted veterans with high health care use, increasing distance from a local VA hospital to a VATC was associated with a significantly increased risk of mortality after hepatic decompensation event, with a 3% increased risk of mortality between 2 populations for every doubling of distance from a local VA hospital to a VATC (HR, 1.03 [95% CI, 1.01-1.04]; P = .001). For example, a waitlisted veteran living 25 miles from a VATC would have a 62.9% (95% CI, 59.1%-66.1%) 5-year adjusted probability of survival from first hepatic decompensation event compared with a 59.8% (95% CI, 56.3%-61.3%) 5-year adjusted probability of survival for a veteran living 100 miles from a VATC.

Discussion

Greater distance between a patient’s local VA hospital and a transplant center was associated with a lower likelihood of being placed on a transplant list when liver transplant was indicated. Once waitlisted, longer distances were also associated with a lower likelihood of receiving a transplant and increased mortality. These findings may be explained by (1) living remotely from a transplant center reducing the likelihood of getting evaluated for transplantation because of long travel times; or (2) reduced ability to proceed with transplantation because of the need for a patient or his or her family members to relocate. When analyzed as a continuous variable, distance had a dose-response relationship with increasing distance resulting in decreased likelihood of being put on a waitlist, receiving a transplant, and having a higher mortality. When analyzed as a categorical variable, distance appeared to have a threshold effect, whereby veterans living more than 100 miles from a VATC had a decreased likelihood of transplantation compared with patients who had their base hospital located within 100 miles of a liver transplant center.

Our study has the advantage of a large sample of patients eligible for a lifesaving health care service. Our findings are consistent with other studies examining the relationship between distance and access to transplant services.\textsuperscript{4,5,7,10} One study did show the opposite effect; an examination of US dialysis patients found a greater likelihood of being waitlisted for renal transplant for patients living farther from a transplant center.\textsuperscript{53} The investigators hypothesized that rural residents treated with dialysis were a highly selected, motivated group to even initiate dialysis given the likely longer distances needed to travel for this service, that physicians in rural areas were aware of the challenges of having rural patients waitlisted due to difficulties in access distant transplant centers, thus expediting transplant referrals, or both reasons.\textsuperscript{13} Our cohort met inclusion criteria simply by having a disease warranting a transplant, thereby avoiding the selection bias that could have influenced that study, which required both the presence of a condition (end-stage renal disease) as well as receiving routine continuous therapy for that disease (dialysis).

Because we could access the medical records for all VA patients in the United States, we could directly estimate the denominator of patients eligible for waitlisting. Prior studies relied on estimates of hypothetical cohorts of patients who might be at risk for receiving a transplant based on census information.\textsuperscript{10,11} Most prior studies assessed care offered at
many centers, with travel times of 15 minutes to 2 hours. Few prior studies evaluated services offered at only a very limited number of transplant centers. Patients in our study who were far away from a VATC did not necessarily reside in rural areas (ie, the Bronx VA Medical Center is >300 miles from the Pittsburgh VATC), resulting in our study being more of an examination of distance rather than urban vs rural. Our results were insensitive to adjusting for VA hospital academic affiliation, suggesting that our findings were related to distance rather than access to advanced liver care services.

Our findings suggest a need to improve access to liver transplantation in the VA. Increasing the number of VATCs is one solution, and the VA National Transplant Program has approved the opening of 2 VATCs: one in Madison, Wisconsin,
and the other in Miami, Florida. However, this will not eliminate problems related to distance from a VATC for many veterans. Other solutions might include (1) streamlining referral to VATCs; (2) using telehealth or allowing local clinician teams to perform initial waitlisting evaluations; (3) active monitoring of liver disease burden at all VA hospitals with assessment of hospitals with low transplant referral rates; and (4) lowering financial disincentives for access to local transplant ser-

Abbreviations: MELD, model for end-stage liver disease; NASH, nonalcoholic steatohepatitis.

<sup>a</sup> Competing risk model of all waitlisted veterans (Veterans Affairs [VA] transplant center [VATC] or non-VATC) with the outcome of transplant and the competing risk of death on the waitlist or within 90 days of waitlist removal. Outcomes reported as subhazard ratios because of the competing risk model. The distance × waitlisting at a VA interaction term was not included in the final multivariable model because it was not significant (P = .22), although waitlisting at a VATC was included in the model even though it was not significant (P = .60). Primary insurance type was also not significant (P = .72). Residential-level poverty was neither independently associated with mortality nor was it a confounder.
services through VA-purchased care (ie, payment of medical services delivered outside of the VHA health system for VHA beneficiaries). Such measures would require significant investment to enact.

**Broader Implications**

This issue of distance and access to care is critical given the focus on accountable care organizations that create large networks of physicians and hospitals. As complex, expensive medical technology evolves, certain services may only be offered at a limited number of sites (eg, proton beam therapy). Although our findings are consistent with prior studies evaluating the association of distance to care, our study is the first, to our knowledge, to demonstrate the adverse consequences of centralization of specialized care at a limited number of sites.

For example, since 2006, hospitals performing bariatric surgeries on Medicare beneficiaries are required to be a designated as centers of excellence. A subsequent single-center study demonstrated that this initiative was associated with reduced access to bariatric surgery based on distance (a subset of patients had to travel distances of >800 miles) despite similar bariatric surgical outcomes at non-centers of excellence vs centers of excellence. However, such an analysis in a national sample of bariatric surgery candidates is practically infeasible due to an inability to nationally define potential candidates based on body mass index data. Similarly, Blue Cross and Blue Shield restricts referrals for complex and rare cancers to centers receiving Blue Distinction. By demonstrating that increasing distance is associated with decreased access to care in a national sample of patients, our analysis may serve as a model of the national association of centralized care on services offered at selected centers. Future work must evaluate whether a causal relationship exists.

**Limitations**

As with any observational study, there may be unmeasured confounding, including that veterans living closer to a VATC have more severe liver disease. However, we specifically identified veterans with decompensated cirrhosis or hepatocellular carcinoma, thus warranting a transplant evaluation. Second, we identified our cohort using International Classification of Diseases, Ninth Revision, codes, not chart review. Even though a subset may be ineligible due to comorbid conditions or psychosocial contraindications (ie, alcohol use or homelessness), this proportion should not differ by hospital or distance. Also, the proportion of veterans waitlisted at a VATC track with those of a single VA hospital study, and a study of all patients hospitalized in Pennsylvania for liver-related conditions. Third, our results may have been related to factors beyond distance (ie, VATC preference for waitlisting patients from their hospital), yet the potential dose-response relationship seen with the continuous distance variable may suggest otherwise. Fourth, distance was measured from the VA hospital. Nonetheless, hospital assignment is based on geographic proximity to a hospital, thus hospital-level distances are representative of the distance a veteran would need to travel. Fifth, categorical analyses were based on distance grouping that was determined after examination of the data; therefore, these analyses should be considered post hoc and the categorical findings exploratory. Sixth, we could not determine hepatocellular carcinoma stage to determine transplant eligibility criteria (Milan criteria), but the results were unchanged with exclusion of all patients with hepatocellular carcinoma.

**Conclusions**

Among VA patients meeting eligibility criteria for liver transplantation, greater distance from a VATC or any transplant center was associated with lower likelihood of being put on a waitlist or receiving a transplant, and greater likelihood of death. The relationship between these findings and centralizing specialized care deserves further investigation.
Health Equity Research and Promotion at the Philadelphia VA Medical Center), for assisting with Organ Procurement and Transplantation and Corporate Data Warehouse cross-referencing. Neither Dr Lo Re nor Mr Roberts received compensation for their role in the study.
